

Viva Questions & Answers.

① Dispatcher Servlet Config :-

- =>
- Dispatcher Servlet acts as front controller for spring based web application
 - It provide mechanism for request processing where actual work perform by configurable, delegate component.
 - It handle all the http request.

② Diff of dispatcher and Backend Controller

=>

Dispatcher	Backend Controller
------------	--------------------

① It read the Servlet Name & Configured in web.xml

① Received the request from the Front-End Controller.

② Tries to find & load the Servlet-Name.xml from Server's file system.

② Execute handler method.
Retrieve the request Data.

③ It Create Spring Context
DispatcherServlet
webApplicationContext.

③ Prepare the bean
Invoke Service
layer which is
then to dao
layer by passing
bean object

④ Return Response to
FrontEndController

③ View Resolver

⇒ • Spring provide View Resolvers which enable you to render models in a browser without tying you to specific view technology.

• The View Resolver provide mapping between view names and actual views

• The view interface address the preparation of the request and hands over view technology.

④ Can Configuration names can be customized?

Yes, we need to create class annotated
@Configuration & register it.
we also use @Conditional annotation.

⑤ JDBC Disadvantages

- =>
- ① It is a slow driver so not used in real time application.
 - ② Because of JDBC connectivity it is an application platform dependent driver.
 - ③ It requires database specific queries, if database change we need to change all SQL statements of query.
 - ④ Performance is not good when we have multiple connections.
 - ⑤ Handling exception with JDBC is a big issue, you need to write multiple nested try-catch blocks.

⑥ What is ORM.

=> Object-relational mapping is a technique in which a metadata descriptor is used to connect object code to a relational database. It manipulates data from the database.

⑦ How do you configure many to many Relations.

- =>
- The association is represent by @ManyToMany annotation.
 - Multiple instance of an entity can be related to multiple instance of another entity. In this mapping any side can be the owning side.
 - It contain composite primary key consisting combination of the primary key of both table.

⑧ Entity lifecycle

=> Four stage

① New

③ Removed

② Managed

④ Detached.

① When an entity object is initially created its state is New

② An entity object become managed when it is persisted to the database via EntityManager's persist method.

5

③ A managed entity object can also be retrieved from the database and marked for deletion using Entity Manager method. then entity object changes its state from managed to Remove.

④ Detached represent entity object that have been disconnected from the EntityManager.

⑤ What is Entity.

⇒ An entity is a lightweight persistence domain object.

It represents a table in a relational database and each entity instance correspond to a row in that table.

⑩ How to validate the no of tickets.

⇒ we use @Min annotation.

(It is required to pass Integer value. must be equal or greater than ^{this} value)

② max annotation.
(required to pass int value equal or smaller)

⑪ How to create custom validation annotation.

=> ① Add dependencies in pom.xml file.

② Create bean class

③ Create Controller class

④ Create validation annotation

⑤ Create validator class

⑥ provide entry of Controller in web.xml file

⑦ Define bean in xml file

⑧ Create request page

⑬ How to prepopulate the sides and show in the Controller class

=> The Controller Base class has a View Data dictionary property that can be used to populate data on Controller and view

It uses key and value of model object.

⑭ What are types of Rollbacks and how we can customize them?

=> Three types of Rollback

- 1) Cascading Rollback
- 2) Cascading Schedule
- 3) Strict Schedule

We can customize using @Transactional annotation.

⑮ How is mvc different from Spring MVC

=> MVC :- MVC is Spring module, you use it for designing web application.

Spring mvc :- It use to build web app. It contain lot of configuration. It has various capabilities. It is Http oriented web application development framework.

(16) How are Spring transactional Beneficial.

- =>
- 1) Provides a consistent programming model across different transaction API such as JDBC, JPA, Hibernate.
 - 2) Supports declarative transaction management.

(17) How to define Scope?

- =>
- Scope refers to the combined objective and requirements needed to complete a project.
 - Properly defining the scope of a project allow managers to estimate cost & time required to project.
 - Two type :- Project management.

(18) Entry Set in Map

=> • `entrySet()` method in java is used to create a set out of the same elements contained in the hash map

• It returns a set view of the hash map. or we can create new view

(19) Diffⁿ Prepared Statement and Statement

=> Statement P. Statement

① used to execute named SQL queries

① used to execute dynamic and parameterized SQL queries

② you can't pass parameters in query

② you can pass

(20) `run()`, `sleep()`

=> The `run()` method of thread class is called at the thread class

Constructed using a Seperate Runnable object..

sleep() is used to stop the execution of current thread.
